

Statistical Issues in Road Safety: Evaluation of Safety Measures

Shrikant I. Bangdiwala, PhD
McMaster University
Hamilton, Canada

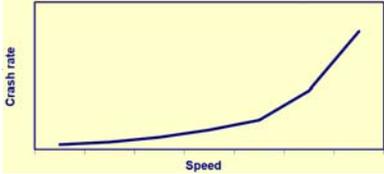

IIT-Delhi 2020 Dec 07

Exercise

- ▶ **Research Question:**
Do lower speeds lead to safer roads?
- ▶ **How do we answer this question?**
 - ▶ What type of study?
 - ▶ How we define 'lower'? How do we define 'safer'?
 - ▶ Who or what do we study? How many?
 - ▶ Who or what do we compare results to? How many?
 - ▶ What data do we collect? How do we measure it? When do we measure? For how long do we measure?
 - ▶ What is a meaningful relationship?
 - ▶ How can we know if what we observe could have been due to chance?

▶ 2

IIT-Delhi 2020 Dec 07

RQ: Do lower speeds lead to safer roads?

- ▶ What do you need to do first?
- ▶ Must recognize the 'sources of variability'
 - ▶ Type of road – i.e. 2-way, straight sector, intersection
 - ▶ Traffic volume?
 - ▶ Presence of median?
 - ▶ What other factors? → consider Haddon Matrix

| PHASE | | FACTORS | | |
|------------|------------------------------------|---|--|--|
| | | HUMAN | VEHICLES AND EQUIPMENT | ENVIRONMENT |
| Pre-crash | Crash prevention | Information attitudes impairment police enforcement | Roadworthiness lighting braking handling speed management | Road design and road layout speed limits pedestrian facilities |
| Crash | Injury prevention during the crash | Use of restraints impairment | Occupant restraints other safety devices crash protective design | Crash-protective roadside objects |
| Post-crash | Life sustaining | First-aid skill access to medics | Ease of access fire risk | Rescue facilities congestion |

Figure 8.3 The Haddon Matrix for road safety (WHO 2006, *Road Safety Training Manual*, Unit 2).

▶ 3

IIT-Delhi 2020 Dec 07

RQ: Do lower speeds lead to safer roads?

- ▶ What do you need to do next?
- ▶ Type of intervention?
 - ▶ How will you lower speeds? – Traffic calming? Car limits? Road limits?
 - ▶ How much lower?
 - ▶ Other structural aspects may have a confounding effect!
 - ▶ How do you know what works?

A Review of Evidence-Based Traffic Engineering Measures Designed to Reduce Pedestrian–Motor Vehicle Crashes

Annals of the New York Academy of Sciences | September 2005, Vol. 95, No. 9

Richard A. Boring, MS, Susan A. Ferguson, PhD, and Anne T. McCart, PhD

J Coll Physicians Surg Pak, 2004 Dec, 14(12):746-7.

Evidence-based interventions for road traffic injuries in South Asia.

Study designs

Source: T D Koepsell, 2001.

▶ 8

IIT-Delhi 2020 Dec 07

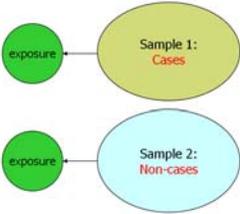

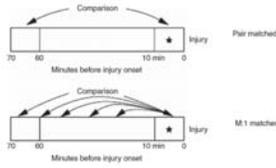

Observational studies – in a given time period

| Type of study | What do they consist of | What information they provide | What statistics they provide |
|-----------------------|--|--|---|
| Case series | <ul style="list-style-type: none"> In-depth examination of a few number of cases  | <ul style="list-style-type: none"> Presence or absence of multiple factors in cases | <ul style="list-style-type: none"> Descriptions of distribution of risk factors |
| Cross-sectional study | <ul style="list-style-type: none"> A sample from a population at a given moment in time  | <ul style="list-style-type: none"> If sample is population based, estimates of the prevalence of the outcome Measures of the association among concurrently measured variables | <ul style="list-style-type: none"> Correlations for continuous variables; odds ratio of exposure or of outcome for categorical variables |

▶ 9

IIT-Delhi 2020 Dec 07

Observational studies – going back in time

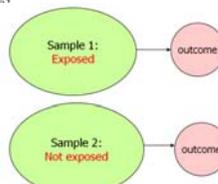

| Type of study | What do they consist of | What information they provide | What statistics they provide |
|----------------------|---|---|--|
| Case-control study | <ul style="list-style-type: none"> Two samples – one of cases, and one of controls Retrospective assessment of exposure in both samples  | <ul style="list-style-type: none"> Measures of the strength of the association between 'caseness' and multiple potential exposure variables  | <ul style="list-style-type: none"> Odds ratio of exposure |
| Case-crossover study | <ul style="list-style-type: none"> Within individual or group sample of times prior to the event | <ul style="list-style-type: none"> Estimates of the effect of immediate exposures on the occurrence of an acute event or outcome | <ul style="list-style-type: none"> Odds ratio of exposure |

▶ 10

IIT-Delhi 2020 Dec 07

Observational studies – going forward in time

| Type of study | What do they consist of | What information they provide | What statistics they provide |
|-----------------------------|---|--|---|
| Cohort study | <ul style="list-style-type: none"> Two samples – one of exposed individuals, and one of unexposed individuals Prospective assessment of occurrence of outcome in both samples | <ul style="list-style-type: none"> If samples are population based, estimates of the incidence of the outcome over time Measures of the risk of multiple outcomes in exposed and unexposed individuals | <ul style="list-style-type: none"> Relative risk of outcome |
| Surveillance and registries | <ul style="list-style-type: none"> All events occurring in a defined population in an extended period of time | <ul style="list-style-type: none"> Since population based, incidence rates for events | <ul style="list-style-type: none"> Descriptions of distributions of events |

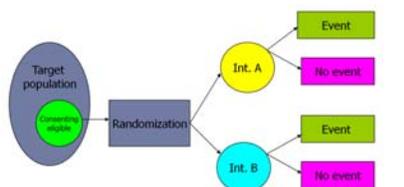

▶ 11

IIT-Delhi 2020 Dec 07

Experimental studies - randomized

| Type of study | What do they consist of | What information they provide | What statistics they provide |
|--|--|--|--|
| Individual randomized controlled trial | <ul style="list-style-type: none"> Individuals are randomly assigned to intervention and control arms; standard protocols are uniformly implemented | <ul style="list-style-type: none"> Valid estimate of the effect of the exposure (intervention) on primary and secondary outcomes | <ul style="list-style-type: none"> Relative risks for binary outcomes; effect on means for continuous outcomes |
| Group or community randomized controlled trial | <ul style="list-style-type: none"> Groups of individuals are randomly assigned to intervention and control arms; standard protocols are uniformly implemented | <ul style="list-style-type: none"> Valid estimate of the effect of the exposure (intervention) on primary and secondary outcomes Since intervention is at the group level, one is not assured individuals actually received the intervention, so that effects are usually smaller Clustering effect leads to correlated data at the individual level that must be accounted for in the analyses | <ul style="list-style-type: none"> Relative risks for binary outcomes; effect on means for continuous outcomes Effects are usually less statistically significant due to the variance inflation from correlated data |

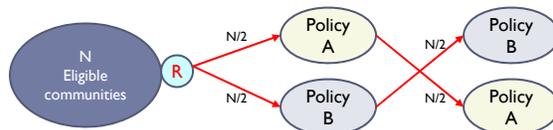

▶ 12

IIT-Delhi 2020 Dec 07

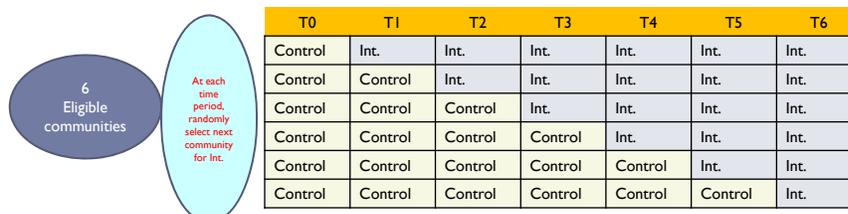

Experimental studies - randomized

Novel group randomized designs for injury research

▶ Cluster cross-over: reversible policy

▶ Stepped-wedge: environmental changes

▶ 13

IIT-Delhi 2020 Dec 07

Experimental studies – non-randomized

| Type of study | What do they consist of | What information they provide | What statistics they provide |
|--|--|---|---|
| Non-randomized comparison intervention study | <ul style="list-style-type: none"> Groups or individuals receive different interventions, but are not randomly assigned; they are self-selected to exposure | <ul style="list-style-type: none"> Biased estimate of the effect of the exposure (intervention) on primary and secondary outcomes | <ul style="list-style-type: none"> Relative risks for binary outcomes; effect on means for continuous outcomes |
| Within-person or within-group before after study | <ul style="list-style-type: none"> A single individual or group acts as its own counterfactual – the outcome after the intervention is compared to the outcome before | <ul style="list-style-type: none"> Within-person or within-group changes due to the exposure (intervention) If there are multiple measures before or after, trends before and after | <ul style="list-style-type: none"> Mean change score for continuous outcomes; McNemar's test for binary outcomes Regression trends before and after |

Bangdiwala SI. Studying the effect of interventions in injury research: experimental design options. *International Journal of Injury Control & Safety Promotion*. 2019 Dec; 26(4):442-447

▶ 14

IIT-Delhi 2020 Dec 07

RQ: Do lower speeds lead to safer roads?

- ▶ What do you need to do next?
- ▶ How 'fewer' is meaningful?
- ▶ How to account for variability and the role of chance? → sample size !! – HOW MANY?
- ▶ It depends!

For estimation

The necessary sample size n when estimating the effect of an intervention in a given group is

- higher if want higher level of confidence
- higher if want higher precision = lower half-width of confidence interval
- higher if there is more variability

Conceptually

$$n \propto \frac{(\text{confidence}) (\text{variability})}{(\text{width})^2}$$

For testing

The necessary sample size n when testing the effect on an intervention is

- higher if want lower level of significance
- higher if want higher power
- higher if differences to detect are smaller
- higher if there is more variability

Conceptually

$$n \propto \frac{(\text{power}) (\text{variability})}{(\text{significance}) (\text{differences})^2}$$

▶ 15

IIT-Delhi 2020 Dec 07

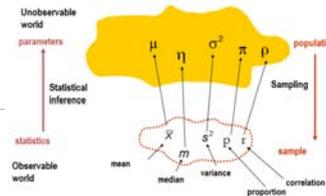

RQ: Do lower speeds lead to safer roads?

- ▶ What do you need to do next?
- ▶ How analyses will be done?
 - Based on study design
 - Based on types of variables
 - based on research question/hypothesis!

▶ 16

IIT-Delhi 2020 Dec 07

Statistical inference

- ▶ **Estimation** of a parameter in a sample → subject to sampling error, measurement error
- ▶ **Inference** from the sample information to knowledge about a population → based on the design, but subject to sampling error, measurement error, and chance
 - ▶ We quantify this chance by assuming a probability model
 - ▶ Using indirect proof → formal statistical hypothesis testing
 - ▶ Using imprecision estimates → construction of confidence intervals

▶ 17

IIT-Delhi 2020 Dec 07

Confidence intervals

Limits on precision:

- ▶ Specify a lower bound and an upper bound within which we are highly confident the true (unknown) value of the parameter lies
- ▶ The interval is centered around our point estimate
- ▶ The width of the confidence interval
 - ▶ Increases with our desire for bigger confidence
 - ▶ Is larger if there is larger variability ('noise' in the system)
 - ▶ Is smaller if based on larger sample sizes

▶ 18

IIT-Delhi 2020 Dec 07

Example

Are 16-year-old drivers with teenager passengers at higher risk of a crash than without other passenger?

$$\text{Relative risk} = \frac{T_f A_{nf}}{T_{nf} A_f}$$

where

T = number of crash involvements for the target age driver (e.g. 16-year-old drivers),

A = number of crash involvements for adult drivers aged 30–59 (i.e. the base driver group),

f = at-fault involvements, and

nf = not-at-fault involvements.

Table 5. Relative risk of fatal crash involvement by driver age and passenger presence (FARS, 1990–1995)

| Driver age | Relative risk | | | | | |
|------------|---------------|--------------------------|--------------|--------------------------|-----------------|--------------------------|
| | All | 95% confidence intervals | Driver alone | 95% confidence intervals | With passengers | 95% confidence intervals |
| 16 | 3.28 | 3.07–3.51 | 2.28 | 2.05–2.53 | 4.72 | 4.32–5.15 |
| 17 | 2.45 | 2.32–2.59 | 1.77 | 1.65–1.92 | 3.52 | 3.26–3.80 |
| 18 | 2.47 | 2.34–2.59 | 1.77 | 1.65–1.90 | 3.66 | 3.40–3.93 |
| 19 | 2.19 | 2.08–2.30 | 1.61 | 1.50–1.72 | 3.23 | 3.01–3.47 |
| 20–24 | 1.86 | 1.82–1.91 | 1.50 | 1.45–1.55 | 2.54 | 2.45–2.64 |
| 25–29 | 1.41 | 1.38–1.45 | 1.28 | 1.24–1.32 | 1.69 | 1.62–1.76 |
| 30–59* | 1.00 | — | 1.00 | — | 1.00 | — |
| 60–69 | 1.03 | 1.00–1.07 | 1.13 | 1.08–1.18 | 0.91 | 0.87–0.96 |
| 70+ | 2.09 | 2.02–2.16 | 2.27 | 2.17–2.37 | 1.93 | 1.84–2.03 |

Preusser et al (1998) The effect of teenage passengers on the fatal crash risk of teenage drivers. *Accident Analysis & Prevention*

*The 30–59 age group is the reference group for relative risk calculations.

► 19

IIT-Delhi 2020 Dec 07

Statistical hypothesis testing

Indirect proof:

- Specify a 'null' hypothesis ('*status quo*') and an 'alternative' hypothesis (our claim)
 - e.g. risk of 16-year old drivers with teenage passengers
 - H_0 : relative risk = 1
 - H_A : relative risk > 1
- Assume the null is correct
- Observe reality (collect data) and see if it conforms with the null being in operation →
 - If probability of observing more H_A favorable data than what we found is **small**, we have evidence to reject the H_0
 - If probability of observing more H_A favorable data than what we found is **not small**, our data are consistent with H_0

► 20

IIT-Delhi 2020 Dec 07

Hypothetical example: Is this driver drunk → evidence?

▶ Hypotheses

- ▶ H_0 : driver **is not** drunk (innocent)
- ▶ H_A : driver **is** drunk (guilty)

- ▶ If evidence is strong supporting drunkenness → declared guilty
- ▶ If evidence is weak supporting drunkenness → declared not guilty

Example of evidence in increasingly incriminating order

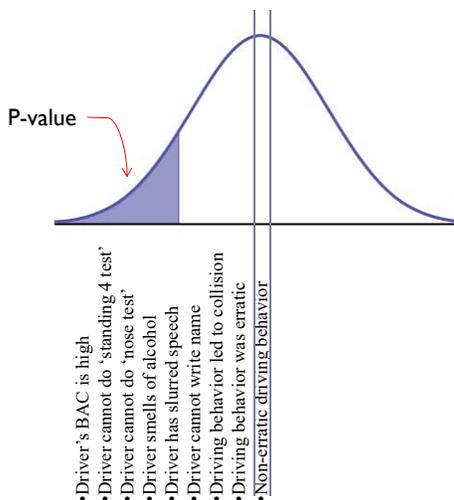

- ▶ Non-erratic driving behavior
- ▶ Driving behavior was erratic
- ▶ Driving behavior led to collision
- ▶ Driver cannot write name
- ▶ Driver has slurred speech
- ▶ Driver smells of alcohol
- ▶ Driver cannot do 'nose test'
- ▶ Driver cannot do 'standing 4 test'
- ▶ Driver's BAC is high

▶ 21

IIT-Delhi 2020 Dec 07

Hypothetical example: Is this driver drunk → evidence?

P-value = probability of an observation that is as or more 'extreme' than the one observed, under the null hypothesis

▶ 22

IIT-Delhi 2020 Dec 07

Dealing with multiple factors

- ▶ **By study design**
 - ▶ Experimental designs – control most factors, let few (one) vary
 - ▶ Observational designs – control few factors, most do vary
- ▶ **By analysis methods**
 - ▶ Stratified analysis – study within similar groups – not always possible
 - ▶ Regression modeling – adjust for variation of several factors

▶ 23

IIT-Delhi 2020 Dec 07

Design *vs.* Analysis

- ▶ **When we control a lot of potential explanatory factors by design, it is not necessary to control much in analysis**
 - ▶ e.g. randomized controlled trials
- ▶ **But when we cannot control much by design, as in observational studies, we need to control variability at the analysis**
 - ▶ Stratified analysis
 - ▶ Multivariate regression models

▶ 24

IIT-Delhi 2020 Dec 07

Dealing with complexities

- ▶ Multiple factors operate on the systems we study
- ▶ We build models – approximations to reality
 - ▶ Risk models – probability distributions
 - ▶ Sampling models – study designs
 - ▶ Regression models – complex systems, relationships

"essentially, all models
are wrong, but some
are useful"

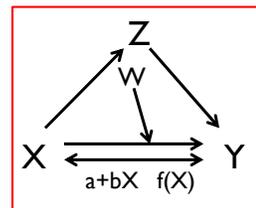

Box, George E. P. & Norman R. Draper (1987)
Empirical Model-Building and Response Surfaces, p.
424, Wiley

▶ 25

IIT-Delhi 2020 Dec 07

Modeling relationships

- ▶ Interest is in studying the relationship between two variables:
 - ▶ Y = dependent variable
 - ▶ X = independent variable
- ▶ How are they related?
 - ▶ Association vs causation
 - ▶ Directly or indirectly (mediated, confounded)
 - ▶ Unencumbered or moderated (modified, interacted)
 - ▶ Linearly or non-linearly
 - Complex system!

▶ 26

IIT-Delhi 2020 Dec 07

Techniques used in statistical modeling

- ▶ **The world is complex!!**
 - ▶ Relationships may not be linear: but may be approximately linear in a narrow range of X
 - ▶ There are multiple variables potentially acting on the relationship: control for them by design or by 'excluding' the variable by limiting the population studied
 - ▶ There is lots of variability: study more so that the 'signal' can be detected despite the 'noise'

▶ 27

IIT-Delhi 2020 Dec 07

Models

- ▶ **Multiplicative models – linearized to be fitted**
- ▶ **Simple**
 - ▶ Fatality rate = deaths/population
 - ▶ Motorization = vehicles/population
 - ▶ Traffic risk = deaths/vehicles
 - $D/P = V/P * D/V$
- ▶ **Complex**
 - ▶ Exponential, mathematical: e.g. Oppe/Koornstra/Lassarre models
 - ▶ Linear models with multiple factors: e.g. statistical regression
 - ▶ Non-linear with multiple factors: structural equation models (SEM), classification and regression trees (CART), ...

▶ 28

IIT-Delhi 2020 Dec 07

Concepts of a 'good' statistical model

- ▶ Concept of 'model should lie among the observed data points' → **goodness of fit**
 - ▶ Minimizing 'residuals' – specifically the sum of squares of residuals
- ▶ Concept of 'model should enhance understanding of the relationship' → **interpretation** must be plausible
 - ▶ Structural equation models
 - ▶ Mathematical relationships based on engineering, physics

Comprehensive model

- ▶ Vogt A and JG Bared, "Accident Models for Two-Lane Rural Segments and Intersection," *Transportation Research Record 1635*, Transportation Research Board, 1998.
 - ▶ Developed accident prediction models that take into account the effects of multiple design elements (horizontal, vertical, cross sectional, etc.). The roads are **two-lane rural roads without medians**.

$$\begin{aligned}
 \hat{y} = & EXPO \times \exp(0.65 + 0.14 STATE - 0.085 LW) - 0.059 SW \\
 & + 0.067 RHR + 0.0085 DD \\
 & \times \left[\sum_i WH \{i\} \exp(0.045 DEG \{i\}) \right] \\
 & \times \left[\sum_j WV \{j\} \exp(0.44 V \{j\}) \right] \quad U.S. Customary Units \\
 & \times \left[\sum_k WG \{k\} \exp(0.11 GR \{k\}) \right]
 \end{aligned}$$

Width & Speed

safety.fhwa.dot.gov/geometric/pubs/mitigationstrategies/chapter3/3_lanewidth.htm

- ▶ Speed is a primary consideration when evaluating potential adverse impacts of lane width on safety. **On high-speed, rural two-lane highways**, an increased risk of cross-centerline head-on or cross-centerline sideswipe crashes is a concern because drivers may have more difficulty staying within the travel lane.
- ▶ **In a reduced-speed urban environment**, the effects of reduced lane width are different. On such facilities, the risk of lane-departure crashes is less. The design objective is often how to best distribute limited cross-sectional width to maximize safety for a wide variety of roadway users. Narrower lane widths may be chosen to manage or reduce speed and shorten crossing distances for pedestrians. Lane widths may be adjusted to incorporate other cross-sectional elements, such as medians for access control, bike lanes, on-street parking, transit stops, and landscaping.

▶ 31

IIT-Delhi 2020 Dec 07

Linear, logistic, Poisson and Cox models

- ▶ If outcome is measured on a continuous scale – e.g. AIS score

$$Y_{AIS} = \beta_0 + \beta_1(\text{speed}) + \beta_2(\text{protective gear}) + \beta_3(\text{age}) + e$$

- ▶ If outcome is a proportion between 0-100 – e.g. probability of seat belt use

$$\ln \text{Odds of Risk} = \ln[\Pr(\text{Use} = 1) / \Pr(\text{Use} = 0)] = \beta_0 + \beta_1(\text{fine\$}) + \beta_2(\text{gender}) + e$$

- ▶ If outcome is a count of events – e.g. number of crashes in a given area over a certain period

$$\ln Y_{\#inj} = \beta_0 + \beta_1(\text{traffic mix}) + \beta_2(\text{road}) + e$$

- ▶ If outcome is time to the occurrence on an event – e.g. time to first crash of newly licensed males

$$\text{Risk} = \Pr(Y_{\text{crash}} < t) = 1 - e^{-\int_0^t h(u) du} \quad \text{where } \ln h(t) = \ln h_0(t) + \beta_0 + \beta_1(\text{training}) + e$$

▶ 32

IIT-Delhi 2020 Dec 07

Key points

- ▶ Life is complex → Transport systems are complex
- ▶ Must understand **sources of variability that lead to uncertainty** → statistics
- ▶ Statistical considerations determine research study designs appropriate to answer specific research questions
- ▶ Injury information has unique features → appropriate statistical methods are necessary
- ▶ Types of research questions:
 - ▶ Diagnosis → observational studies
 - ▶ Evaluation → experimental studies

▶ 33

IIT-Delhi 2020 Dec 07

Key points

- ▶ Statistical methods for inference help us
 - ▶ ‘See the signal amidst the noise’
 - ▶ Understand information in the presence of uncertainty from variability and chance
 - ▶ Assuming data is of quality!
- ▶ We construct models to ‘make sense out of reality’ (“what structures gave us these data”)
- ▶ **All** models are simplifications of reality → have limitations stemming from assumptions
 - ▶ Statistical models incorporate **uncertainty (chance) and variability**
- ▶ Models to evaluate effectiveness of interventions

▶ 34
